Effect of the Cable Capacitance of Long Control Cables on the Actuation of Contactors

Technical Paper
Dipl.-Ing. Dirk Meyer
The contactor is the most important switching device in industrial and commercial applications. Its importance has further increased due to the influence of automation. This has given rise to some significant advancements in the development of contactors, of which the user is often not aware. For example, the power required for switching has been considerably reduced in recent years due to the use of integrated actuation electronics.

Despite the many benefits made possible by the reduced power consumption, such as
- Energy savings
- Use of smaller control transformers
- Longer service life of control contacts

the reduced power requirements must be particularly taken into account with applications involving long control cables. Reliable contactor disconnection on actuation of the command device also depends on cable length, due to the cable capacitance between the command device and the contactor coil.
1. Cable capacitances

In certain circumstances, long control cables in AC actuated control circuits may prevent the disconnection of contactors due to the cable capacitance present.
Even if the command contacts are open, the coil current can still flow due to the cable capacitance so that the contactor remains in the On position if sufficient sealing current is present.
The effect of cable capacitance depends on the design of the control current circuit:

1.1 Capacitance of control cables

A guide value for control cable capacitances between two conductors is approx. 0.3 µF per km for two-wire control, and approx. 0.6 µF per km between three conductors for three-wire control. The following equation should be used:

- CL = 0.3 (µF/km) x l (km) (1.3) Two-wire control
- CL = 0.6 (µF/km) x l (km) (1.4) Three-wire control

On disconnection, C_{12} and C_{13} are switched in parallel (C_{11} is bridged by Q11). However, the specific values depend on the cable used and may therefore vary. If necessary, obtain the cable capacitance from the manufacturer.
When laying control cables together with other lines (e.g. in the cable duct), the cable capacitance can no longer be calculated. The capacitive currents must be measured.
2. Limit capacitance of a contactor

The maximum capacitance at which the contactor stays switched on in the new condition despite the off command can be calculated using the equation below:

\[ C_{\text{max}} = \frac{b}{1 + a} \cdot \frac{P_H \cdot 10^6}{\omega \cdot U_C^2} \]  (2.0)

with

\[ a = \frac{U_{AB}}{U_C} = 0.4 \]
\[ b = \frac{I_{AB}}{I_C} = 0.25...0.35 \]

\( U_{AB} \) = minimum drop-off voltage in V
\( I_{AB} \) = Sealing current with a minimum drop-off voltage in A
\( P_H \) = Rated sealing current of the contactor in VA
\( U_C \) = Rated control supply voltage in V

At 50 Hz and a permissible rated control supply voltage 110% times rated voltage based on equation 2.0:

\[ C_{\text{max}} = 500 \cdot \frac{P_H}{U_C^2} \] [\mu F]

At 60 Hz the values must be reduced by 20%.

3. Determining the maximum permissible control cable lengths

In order for a contactor to switch correctly, \( C_c \) must be less than \( C_{\text{max}} \).

If equations (1.3) and (1.4) are related to equation (2.1), the following values are produced for 50 Hz networks:

\[ l_{\text{zul}} = 0.85 \cdot 10^6 \cdot \frac{P_H}{U_C^2} \] [m]

Three-wire control (3.1)

\[ l_{\text{perm}} = \text{maximum permissible control cable length in m.} \]

With 60 Hz networks the values for (3.0) and (3.1) must be reduced by 20%.
4. Measures to counteract excessive cable capacitance

Several solutions are possible if the engineering of an installation determines that the contactors will not drop out due to excessive cable capacitance:

- Use of contactors with higher coil sealing power
- Use of DC operated contactors
- Reduction of the control supply voltage (allow for voltage drop)
- Laying the supply cable near the command contacts
- An additional NC contact for two-wire control and NO contact for three-wire control are used to short the coil. An additional cable is required for this. This considerably increases the break times of the contactors

- Parallel switching of a resistance. The resistance is calculated as follows:

\[
R = \frac{1000}{C_L} \quad [\Omega] \quad C_L \text{ in } \mu\text{F} \quad (4.1)
\]

The power of the resistance is:

\[
P = \frac{U_C^2}{R} \quad [\text{W}] \quad (4.2)
\]

It must be taken into account that the resistor increases the total heat dissipation of the circuit.

**Maximum permissible cable length in m for Two-wire control 50Hz | Three-wire control 50Hz | Two-wire control 60Hz | Three-wire control 60Hz**

Maximum permissible single control cable length for a rated control supply voltage of 230V and 120V and a maximum control supply voltage of 1.1 x UC for 50 Hz and 60 Hz mains frequency.
Eaton Corporation

Eaton is a leading power management company. Eaton operates worldwide with products, systems and services in the electrical, hydraulic, aerospace, truck and automotive sectors.

Eatons Electrical Sector

Eatons Electrical Sector is the worldwide leader in products, systems and services for energy distribution, safe electricity supply and automation in industrial, residential and purpose-built buildings, public facilities, energy providers, commerce and OEMs.

Eatons Electrical Sector includes the brands Cutler-Hammer®, Moeller®, Micro Innovation, Powerware®, Holec®, MEM® and Santak®.
